

### **DESCRIPTION OF MAP UNITS**

Artificial fill (Holocene)—Brown (10YR 6/2) mostly silt, sand, and chert gravel; locally derived from loess, alluvium, and map unit QTg. Fill occurs along roadways and reclaimed sand and gravel quarries, and as building pads. Thickness generally 1-2 m,

but 20±10 m in reclaimed quarries and some bridge approaches **Alluvium (Holocene)**—White (10YR 8/2) sand, brown (10YR 6/2) clayey silt, and minor tan (10YR 7/4) gravel. Sand is very fine grained to coarse-grained quartz with chert. Thickbedded, basal point bar sands are overlain by alternating thin beds of sand and silt and capped by overbank clayey silt with beds having no apparent bedding. Bottom of basal sand not visible but floodplain borings indicate it is as much as 7 m thick, the overlying alternating sand and silt section is 1–2 m thick, and the top clayey silt unit is 1–4 m thick. Total alluvial thickness generally <10 m. This alluvium is restricted to the Wolf River floodplain (W.S. Parks, unpub. mapping, 1977; Broughton and others, 2001) Qa Alluvium (Holocene)—Reworked loess consisting of brown (10YR 6/2) silt and minor mixed

Fletcher Creek and tributaries to Wolf River consist of reworked loess. Channel beds are covered with thin sand and gravel bars Loess (late Pleistocene)—Brown (10YR 6/6) and light-brown (10YR 7/4) silt with <10 percent sand and <10 percent clay (Spann, 1998). Regionally, loess is predominantly quartz with minor amounts of plagioclase, orthoclase, and dolomite (Gelderloos, 1996).

Terrace deposit (Pleistocene)—White (oxidized orange), dense, crossbedded, mediumgrained sand capped by loess silt (Saucier, 1987) Gravel ("Lafayette Gravel" of Hilgard, 1892, early Pleistocene and Pliocene?)—Shown in cross section only. Highly oxidized, fine- to coarse-grained sand, chert gravel, and minor silt and clay; thickness 0–20 m. Thickness varies because upper and lower

1991). Upper part of unit exposed in some stream banks and in construction Claiborne Group, upper part (Eocene)—Shown in cross section only. Clay, silt, and sand. Generally consists of clay and silt, but locally may consist predominantly of fine sand

### INTRODUCTION

The map locates surficial deposits and materials. Mapping them is the first step to assessing the likelihood that they could behave as a viscous liquid (liquefy) and (or) slump during strong earthquakes. This likelihood depends partly on the physical characteristics of the surficial deposits (Youd, 1991; Hwang and others, 2000), which are described here. Other possible uses of the map include land-use planning, zoning, education, and locating aggregate resources. The Ellendale quadrangle is one of several quadrangles that were mapped

The City of Memphis lies within the upper Mississippi embayment, which is seismically active (Schweig and Van Arsdale, 1996) and near the New Madrid Seismic Zone (NMSZ) (fig. 2). Proximity to the NMSZ raises concerns that if earthquakes as strong as those that occurred near New Madrid, Mo., in 1811–1812 were to occur again, life and infrastructure in Memphis would be at risk (Hamilton and Johnston, 1990). The evidences suggestive of a seismic risk for the Ellendale quadrangle are: (1) probable earthquake-induced liquefaction features (sand dikes) exist in Wolf River alluvium inside Memphis city limits (Broughton and others, 2001), (2) severe damage in the area of present-day Memphis was caused by an 1843 earthquake in the NMSZ, near Marked Tree, Ark. (Stover and Coffman, 1993), and (3) in the mid-continent, earthquake energy waves travel long distances outward from their source, compared to distances of wave transmission from earthquakes of comparable magnitude in California (Johnston and Kanter, 1990; Tuttle and Schweig, 1996).

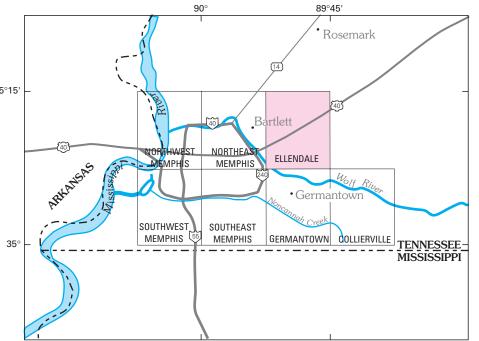

Figure 1. Locations of quadrangles for which the geology has been mapped recently as part of the National Earthquake Hazards Reduction Program of the USGS.

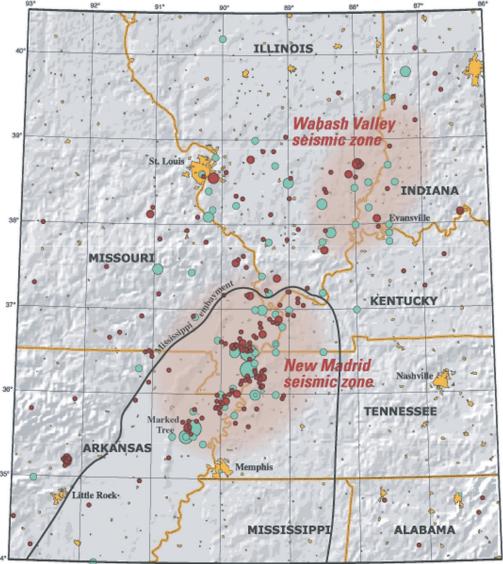

Figure 2. New Madrid and Wabash Valley seismic zones, showing earthquakes as circles. Red, earthquakes that occurred from 1976 to 2002 with magnitudes >2.5, located using modern instruments (University of Memphis). Green, earthquakes that occurred prior to 1974. Larger circle represents larger earthquake. Modified from Gomberg and Schweig (2002).

Note: Drill holes are shown by vertical lines and numbers. Numbers are the

Shelby\_id numbers of the Shelby County database of the Groundwater Institute, University of Memphis. Total depth of some holes exceeds the vertical dimension of the cross section and is not plotted. Some holes projected into cross section
